Design Considerations

Overall Design Flow

In our design, we used the Model View Controller design pattern to avoid rigidity and immobility. In our application, we divide all code into 5 subpackages: app, boundary, controller, model, and view. App contains only the Main file of the project, which is used to run the whole MYSTARS system. Boundary contains all classes that deal with interactions with the user and file system. Controller contains control classes that operate the entities and controls the view to print messages. For example, the "Student Controller" class carries the logic needed for implementing all the functions, such as "Add Course", "Drop Course", "Change Index Number of Course", when a user login as a student. "Student Controller" will call "Student" which is a Model, and get all the data stored in a particular student object. It will call "Student View" to display the information of this student object. Models deal with all the data stored inside an entity and only contain methods that modify the data (setter and getter). For example, the "Student" class is a Model. It contains all the necessary get and set methods to take in and return data of students such as "getAccount", "getCurrentAu", "setAccount", "setCurrentAu". Last but not least, the view takes in the model and prints all information stored inside. For example, "StudentView" class to display students' information.

In our MYSTARS system, we have 2 types of user, administrator and student. We designed a model class for each of them to store their data read from the csv files. Since we need to perform a number of operations on the two types of users, we created Controllers for the student class and the administrator class, which handles all requests from their menu (in the main). Considering that student information and admin information both need to read data from the csv files, and they both perform a series of similar operations like login, read information, use their View classes to produce output to the console and the csv files etc. We wrote their shared methods in one superclass called AccountController which handles the shared methods of the two controllers.

The course class and index class are used to store and handle course data and index data. Course is a collection of indices, the collection of indices have some shared attributes of indices like the course name, the lecture time and venue, etc which will be stored in course class. Indices store

the individual data like vacancies and index numbers. Since we need to perform a lot of operations on index, including checking index clashes, fixing waitlists if there is vacancy, we created an index controller, which handles all index operations and generates output through Index View class.

We created some additional boundary classes to deal with different kinds of inputs and outputs. They are divided by their functionalities and they all have only one or two functions to keep their responsibility simple (Single Responsibility Principle). We have a Notification interface that provides a "send()" method to send notification to students. It is implemented by EmailSender class which sends email to the student NTU email account, this allows easy extension as adding other methods of notification only requires creating a class that implements Notification. The FileHandler class tries to read from and write to databases. The MainIO class constructs the courses and indices collection for the main program. The InputScanner class tries to deal with all simple numeric inputs and eliminate any invalid inputs.

In conclusion, since every class does its own work, making our program structure clear.

Principles

1. Single Responsibility Principle (SRP)

We designed our classes such that each class only has one responsibility. We have split up the bigger classes into three classes. Model class only contains the setters and getters, it is responsible for the modification and retrieval of data of the object. View class contains all the reusable print functions, for example, StudentView class contains functions to print student information and functions to print the all courses a particular student is registered etc. The Controller class handles all the functions that are logic intensive, these methods are built using the model and view class, for example, StudentController class contains addCourse method and readStudent method.

2. Open Closed Principle (OCP)

In our design, the Notification Interface makes use of the Open Closed Principle. It has a send method that takes in a target account and a piece of text. The interface is then implemented by EmailSender class, which implements the send method and sends an email

to the target account. It is open for extension in the way that we can add more classes to implement the interface, for example, a WhatsAppSender class that sends WhatsApp messages. It is closed for modification such that the new classes would not affect any of the previous classes.

3. Dependency Injection Pattern (DIP)

The higher level classes in our design are independent of the lower level classes. For example, AccountController is a higher level class compared to StudentController and AdminController. AccountController is not dependent on these two classes and it can be reused quite simply should there be a new user type.

Assumptions made

- All courses have 2 lectures. Courses with one two hours lecture could be split into two continuous one hour lectures.
- All labs are either on odd or even week.
- Email sent only when student move from waitlist to registered
- AU of all courses are between 1 and 10.
- The maximum AU students can register or put onto waitlist is 21. Sum of number of AU of registered course and number of AU of waitlisted course cannot exceed 21.

Testing

Admin Functions

Function	Input	Expected Output
Login	Successful login Account: admin1 Password: pwd1	Account: admin1 Password: Logged in successfully. Current account: admin1 Please select one of the functions: 1. Edit Student Access Period 2. Add Student 3. Add/Update A Course 4. Check Available Slot For An Index Number 5. Print Student List By Index Number 6. Print Student List By Course 7. Exit
	Unsuccessful login Account: wrongacc OR Password: wrongpwd	Account: wrongacc Password: Login failed. Check account and password and try again. Logging in as admin (press enter to exit) Account:
